1. Materials and Methods

1.1 Experimental Procedure

A nitric based-precursor containing Ce, La, and Mn ions was prepared from the dissolution of electronic waste materials, followed by purification steps. The elemental composition of the precursor was analysed by inductively coupled plasma optical emission spectroscopy (ICP-OES, Perkin Elmer Optima DV7300), and is available in **Table S1**, showing the remarkable high concentration of La and Ce compared to Mn, with the ratio of 63:7.5:0.9, respectively. The ppm concentration of Mn is due to the fact that Mn removal was the last step of purification for the extraction of rare earth oxides (REOs) from the precursor in the recycling process. This trace amount of Mn was deposited using chronoamperometry technique, via a potentiostat/galvanostat (VSP-300, BioLogic) workstation, on the surface of fluorine-doped tin oxide (FTO) coated glass with the exposed surface area of 1.8-1.9 cm^2. Before the deposition, the FTO substrate was carefully rinsed with ethanol, acetone, and deionised water in a sonicator. Electrodeposition experiments were conducted using a three-electrode configuration, in which FTO was used as working electrode (WE), a Pt spiral wire as the counter electrode (CE), and standard calomel electrode (SCE) as the reference electrode (RE). Thin films were electrodeposited from the solution at 70°C, since at this temperature the rapid extraction of Mn resulted in the formation of an adherent and smooth thin-film. The electrodeposition potential was kept constant at 1.0 V vs. SCE to pass a specific amount of electric charge (in mC) for every cm^2 of area; hence, the deposited weight in all samples was comparable. After electrodeposition, the prepared electrode was thoroughly rinsed by distilled water and dried in ambient air. To double-check the deposited weight, some samples were weighted using a five-digit microbalance with the accuracy of ±10 μg.
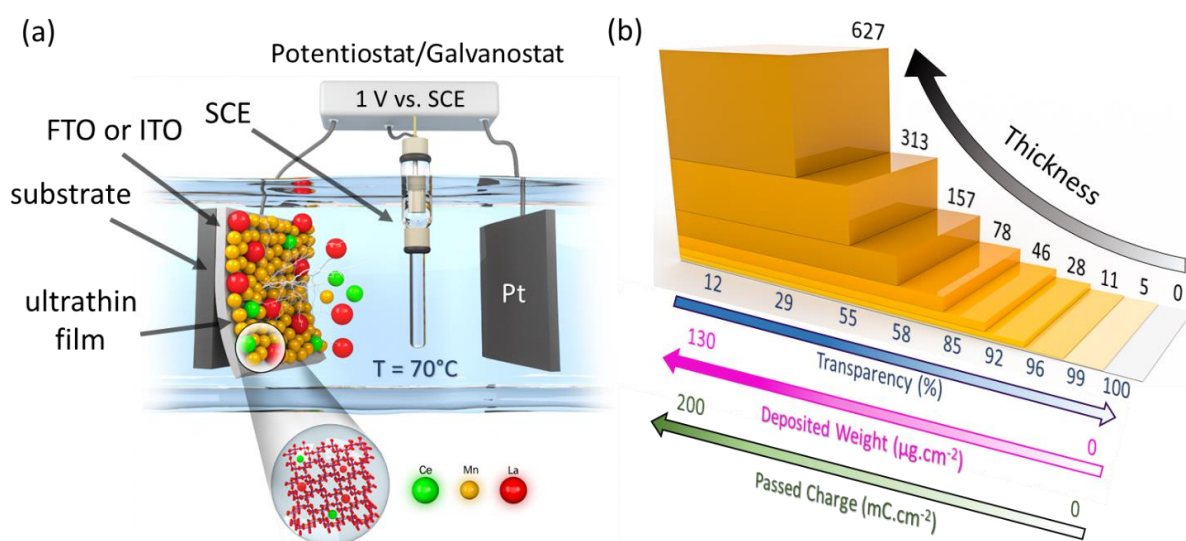

Figure S1. Schematic of **(a)** the chronoamperometric synthesis of $Mn_{1-x-y}(Ce_xLa_y)O_{2-\delta}$ ultrathin films on FTO, and **(b)** the resultant $Mn_{1-x-y}(Ce_xLa_y)O_{2-\delta}$ ultrathin films at different thicknesses.

Table S1. ICP Elemental analysis of the precursor for $Mn_{1-x-y}(Ce_xLa_y)O_{2-\delta}$ electrodeposition.

Element	Ce	Fe	La	Mn	Nd	Ni	Pr
Concentration (mg.L^{-1})	7571	0.35	63160	860	4604	698	1287

For comparing the results of ultrathin films made of $Mn_{1-x-y}(Ce_xLa_y)O_{2-\delta}$, ultrathin films made of MnO_{2-x} were also fabricated. The precursor for the MnO_{2-x} films was prepared from the leaching of pure metallic Mn (extracted from the recycling of spent zinc-manganese oxide batteries) in the glacial acetic acid. The concentration of Mn and pH of the solution were 4.6 g.L and 5.0, respectively.

The electrochemical performance of the as-synthesised thin-film was examined in 2 M KOH aqueous solution using a three-electrode cell configuration at room temperature. Cyclic voltammetry (CV) and galvanostatic charge-discharge (GCD) tests were performed in the range of -0.3 to 0.5 vs. SCE/V using the three-electrode cell configuration in which the thin-film electrode was used as the WE. Electrochemical impedance spectroscopy (EIS) was conducted at 0.0 vs. SCE/V and 10 mV of amplitude between 100 kHz to 100 mHz, after leaving the working electrode in the solution for 20 min to reach a constant open circuit potential (OCP).

To access the performance of the optimum $Mn_{1-x-y}(Ce_xLa_y)O_{2-\delta}$ thin-films in a two-electrode system, the CE and RE were replaced by a similar WE to make a symmetric capacitor. In the second step of development, a solid-state device was fabricated including two identical thin-films coated on two FTOs and solid-state LiCl/PVA electrolyte as an interlayer. The solid-state gel electrolyte was made after thoroughly mixing (via a magnet stirrer) of 0.43 g LiCl, 1 g PVA, and 10 ml deionised water at 85 °C for around 1 hr. Small droplets of gel electrolyte, enough to cover the whole surface, was applied on the surface of both films and two FTOs were gently squeezed together under a mild presser using paper clips for 24 hr. In the third step of development, the optimum thin-film was electrodeposited on the surface of indium tin oxide (ITO) coated polyethylene terephthalate (PET) flexible substrate with the resistance of 30 Ω.square^{-1}. Prior to deposition, the ITO coated PET was washed and treated in acetone, ethanol, and deionised water before electrolytic deposition. The deposition procedure was similar to that of FTO. These three symmetric devices were employed for electrochemical analysis. The energy density (E) and power density (P) of the two-electrode device were calculated using the following equations[1]:

$$E \text{ (wh kg}^{-1}) = \frac{C \times (\Delta V)^2}{7.2} \quad \text{(Eq. S1)}$$

$$P \text{ (W kg}^{-1}) = \frac{3600 \times E}{\Delta t} \quad \text{(Eq. S2)}$$

Where C (F.g^{-1}) is the specific capacitance, ΔV (V) is the potential window, and Δt (s) is the discharge duration in CD analysis.

1.2 Advanced characterisation equipment and parameters

The morphology of samples was observed by field-emission scanning electron microscopy (FE-SEM, NanoSEM 450 NOVA). Raman data were obtained by a Renishaw inVia Raman microscope (Gloucestershire, UK), which is equipped with a He-Ne green laser (λ=514 nm) and diffraction grating of 1800 g mm^{-1}. Before characterisation, the equipment was calibrated against the Si peak at ~520 cm^{-1}. The Raman spectra were obtained for the range 100-800 cm^{-1} and spot size ~4 μm. The data were analysed by Renishaw WiRE 4.4 software. Transparency and bandgap of the films were analysed using ultraviolet-visible spectroscopy (UV–Vis, Perkin Elmer Lambda 35 equipped with UV Winlab V.6 software) in the presence of FTO coated glass as the standard sample. The bandgap of samples calculated using well-known Kubelka-Munk function and illustrated in a Tauc plot. To find out the chemical state and oxidation number of elements, X-ray photoelectron spectrometer (XPS, Thermo Scientific ESCALAB250i with monochromated Al Kα line (1486.68 eV) as the X-ray source) analysis was utilised under high vacuum (2–9 mbar) with 20 eV passing energy. The thickness and composition of the films were subjected to time-of-flight secondary ion mass spectroscopy (TOF-SIMS) under positive polarity by Bi_3^+ at 30 KeV and sputtered by Cs^+ beam of 1000 eV. EPR analysis was implemented using a Bruker EMX X-Band ESR Spectrometer with a constant frequency at 9.8520 GHz. The corresponding data were obtained at centre Field of 3400 mT, modulation amplitude at 4G,

and microwave power of 20 mW. Further, the EPR signal and hyperfine processing were carried out using Bruker Xenon software.

In all advanced characterisation methods expect EPR, thin films were directly used. The powder samples for EPR analysis were prepared by scratching the surface of films using a sharp knife.

1.3 DFT calculations

Spin-polarized density functional theory (DFT) [2] calculations were performed to theoretically characterise the electronic band properties of the α, β, and δ polymorphs of MnO_2 as well as of Ce/La inserted α-MnO_2. The PBEsol+U exchange-correlation energy functional [3] was used as it is implemented in the VASP software [4]. A "Hubbard-U" scheme [5] with U = 3 eV was employed for better treatment of the localized Mn 3d and Ce 4f electronic orbitals. We employed the "projector augmented wave" method [6] to represent the ionic cores by considering the following electrons as valence: Mn 3d and 4s; O 2s and 2p; Ce 4f, 5d, 6s, and 4d; and La 5d, 6s, and 4d. Wave functions were represented in a plane-wave basis truncated at 650 eV. For integrations within the first Brillouin zone, we employed Monkhorst-Pack k-point grids with a density equivalent to that of a 10x10x16 mesh for the bulk β-MnO_2 unit cell. Periodic boundary conditions were applied along the three lattice vectors defining the simulation supercell. Geometry relaxations were performed with a conjugate-gradient algorithm that optimised the ionic positions and volume and shape of the simulation cell. The relaxations were halted when the forces in the atoms wereall below 0.01 eV·Å^{-1}. By using these technical parameters, total energies were converged to within 0.5 meV per formula unit. The range-separated hybrid HSE06 exchange-correlation functional [7] was used to accurately estimate the electronic properties of the equilibrium geometries determined at the PBEsol+U level.

2. Results
